- | | | |
|----|--|---|
| 1. | First, we load the bio3d package using library(bio3d). Then, we have R read the PDB files using read.pdb(). | 1 |
| 2. | We trim each protein into only chain A and alpha carbon atoms using trim.pdb(). Then, we extract B-factor from alpha carbon. | 2 |
| 3. | Then, we combine the B-factor vectors into a protein matrix using rbind(). | 2 |
| 4. | Make a protein cluster using hclust(). | 2 |
| 5. | Then, we plot the cluster diagram using plot(). | 3 |
| 6. | To generalize this process, we wrap it into a function called analyze_proteins(). We use lapply() to apply the trimming and B-factor extraction to each protein. do.call() combines the results into a matrix. | 3 |
| 7. | To run the function, we first create a list of protein objects like protein_list <- list(s1, s2, s3) and then call analyze_proteins(protein_list). The function will automatically produce a dendrogram showing how similar the proteins are based on their B-factors. | 4 |

- 1. First, we load the bio3d package using library(bio3d). Then, we have R read the PDB files using read.pdb().**

```
library(bio3d)  
  
s1 <- read.pdb("4AKE") # kinase with drug
```

```
Note: Accessing on-line PDB file
```

```
s2 <- read.pdb("1AKE") # kinase no drug
```

```
Note: Accessing on-line PDB file
```

```
PDB has ALT records, taking A only, rm.alt=TRUE
```

```
s3 <- read.pdb("1E4Y") # kinase with drug
```

```
Note: Accessing on-line PDB file
```

2. We trim each protein into only chain A and alpha carbon atoms using trim.pdb(). Then, we extract B-factor from alpha carbon.

```
s1.chainA <- trim.pdb(s1, chain="A", elety="CA")
s2.chainA <- trim.pdb(s2, chain="A", elety="CA")
s3.chainA <- trim.pdb(s3, chain="A", elety="CA")

s1.b <- s1.chainA$atom$b
s2.b <- s2.chainA$atom$b
s3.b <- s3.chainA$atom$b
```

3. Then, we combine the B-factor vectors into a protein matrix using rbind().

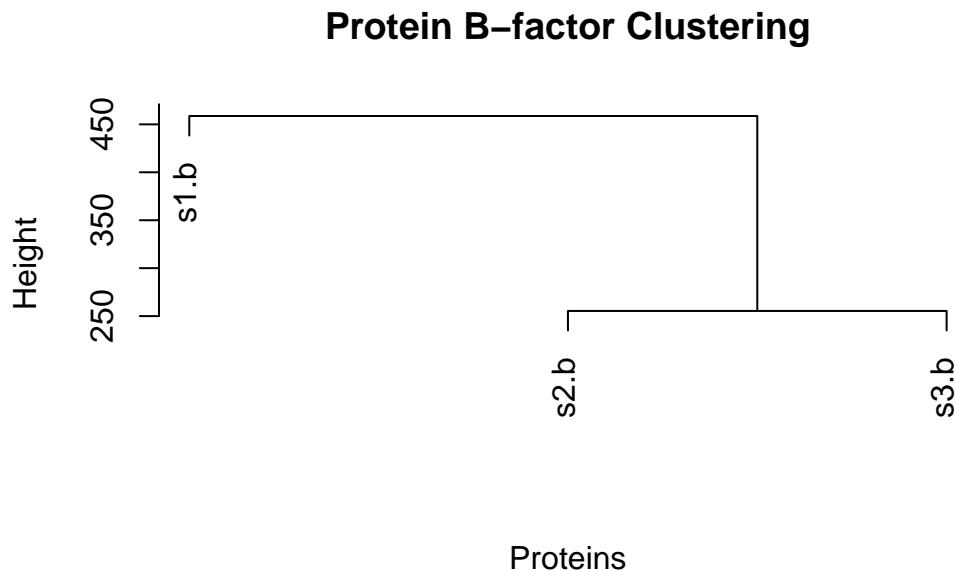

```
protein_matrix <- rbind(s1.b, s2.b, s3.b)
```

4. Make a protein cluster using hclust().

```
protein_dist <- dist(protein_matrix)
hc <- hclust(protein_dist)
```

5. Then, we plot the cluster diagram using `plot()`.

```
plot(hc,
  main = "Protein B-factor Clustering",
  xlab = "Proteins",
  sub = "")
```

6. To generalize this process, we wrap it into a function called `analyze_proteins()`. We use `lapply()` to apply the trimming and B-factor extraction to each protein. `do.call()` combines the results into a matrix.

```
analyze_proteins <- function(pdb_objects) {
  bfactor_list <- lapply(pdb_objects, function(pdb) {
    chainA <- trim.pdb(pdb, chain="A", elety="CA")
    chainA$atom$b
  })
}
```

```
protein_matrix <- do.call(rbind, bfactor_list)
rownames(protein_matrix) <- names(bfactor_list)

protein_dist <- dist(protein_matrix)
hc <- hclust(protein_dist)

plot(hc,
      main = "Protein B-factor Clustering",
      xlab = "Proteins",
      sub = "")
}
```

7. To run the function, we first create a list of protein objects like protein_list <- list(s1, s2, s3) and then call analyze_proteins(protein_list). The function will automatically produce a dendrogram showing how similar the proteins are based on their B-factors.

```
protein_list <- list(s1, s2, s3)
analyze_proteins(protein_list)
```

Protein B-factor Clustering
